# Contents

# Definitions:

- **OOP** is a programing technique that focuses on the data(=objects) and on the interfaces to that object.
- **Object:** Is the instance of the class
- **Object Class:** is the ***ultimate super class***. Every class you ever make in Jave will automatically inherit from it.(equals, toString, and getClass)
- **Classes:** A class is the template or blueprint from which objects are made.
  - Static variable:
    - Belong to the class
    - Accessed by: ClassName.VARIABLE_NAME
- **Superclass:** class above another in a hierarchy of classses
- **Subclass:** inherits form parent and is a version of the parent class
- **Encapsulation(sometimes called information hiding):** is simply combining data and behavior in one package hiding the implementation details from the users of the objects.
- **Instance variables:** are variables defined in a class, but outside the body of methods. Instance variables are filled when each object is instantiated and belong the object.
- **Class Variables:** belongs to the class and the value in that variable is shared by every instance of the class by the class itself.
- **Constructor:** set data's values
- **Methods:** Manipulate and access data
- **Public:** is keyword which declares a member's access as public.
- **Private:** is a Java keyword which declares a member's access as private.
- **Static:** object belongs specifically to the class, instead of instances of that class.
- **Is-a:** inheritance/interfaces
- **has-a:** composition/aggresgation

Three key characteristics of objects:

- **The object's behavior**
- **The object's state**
- **The object's identity**

# Array:

```
int[]array= new int[20]; // allocating memory for array. it will be fixed sized
array[0]=5; //declaring first element array

//for loop - if nums is Array
for (int i = 0; i < nums.length i++){
  //nums[i];
}

//for each loop
for (int i: nums){
  //do stuff with i
}
```

## ArrayList:

```
ArrayList<String>words=new ArrayList<String>();

ArrayList<Integer>num=new ArrayList<Integer>();

LinkedList<String> ll = new LinkedList<>();

num.add(1);

num.get(0); // we need put index

//remove element base on index
num.remove(1);

//for loop - if nums is ArrayList
for (int i = 0; i < nums.size(); i++){
  //nums.get(i);
}

//for each loop
for (int i: nums){
  //do stuff with i
}
```

## HashMap:

```
Map<String,String>myMap=new HashMap<>();

// add key
myMap.put("Hadi","21");

// get the value of the key
myMap.get("Hadi");

// remove the key
myMap.remove("Hadi");

// clear whole Map
myMap.clear();

// get the size
myMap.size();

// Different way of loop
for (String name: myMap.keySet()){
  System.out.println(age);
}

for (String age: myMap.values()){
  System.out.println(age);
}

for(Map.Entry<String,String>entry:myMap.entrySet()){
  String key=entry.getKey();
```

```
  String value=entry.getValue();
}
```

### Example:

```
class Trainer{
    private String id;
    private String name;

  public  Trainer(String id, String name)
    {
        this.id = id;
        this.name = name;
    }
    public String getID() { return id; }
    public String getName() { return name; }
}
public static void main(String[]args){

  Map<String,Trainer> train=new HashMap<>();

  train.put("red",new Trainer("40","Hadi"));
  train.put("blue",new Trainer("401","Had"));
  train.put("Yellow",new Trainer("402","Ha"));
  train.put("black",new Trainer("403","H"));

  for(Map.Entry<String,Trainer>data:train.entrySet()){

    System.out.println("Color: "+(String)data.getKey()+" id: "+(String)data.getValue().getID());
  }

}
}
```

### Example:

```
import java.util.LinkedList;
import java.util.List;
import java.util.Map;

class ExampleMap
{
   public static List<String> highEnrollmentStudents(
      Map<String, List<Course>> courseListsByStudentName, int unitThreshold)
   {
      List<String> overEnrolledStudents = new LinkedList<>();

      /*
         Build a list of the names of students currently enrolled
         in a number of units strictly greater than the unitThreshold.
      */

      for(String name:courseListsByStudentName.keySet()){
```

```
         int sum=0;
         for(Course course:courseListsByStudentName.get(name)){
            sum+=course.getNumUnits();
         }
         // int unit=courseListsByStudentName.get(name).getNumUnits();
         if (sum>unitThreshold){
            overEnrolledStudents.add(name);
         }

      }

      return overEnrolledStudents;
   }
}
```

# Overriding:

## toString():

```
  public String toString(){ return name;}
```

## equals:

```
public boolean equals(Object o){
  if (o==null){return false;}
  if (o.getClass()!=this.getClass()){return false;}
  Theater t=(Theater)o;
  return t.seatingCapacity==seatingCapacity && t.numberTicket==numberTicket && t.name.eqals(name);
}
```

**OR**

```
public boolean equals(Object o){
  if (o==null){return false;}
  if (o.getClass()!=this.getClass()){return false;}
  Theater t=(Theater)o;
    if(name==null)
        result=t.name==null;
    else
        result=t.name.equals(name);
  return result && t.seatingCapacity==seatingCapacity && t.numberTicket==numberTicket;
}
```

## Hash Code:

```
public int hashCode()
    {
            int hash = 1;

            hash = hash * 31 + studentLoans; //can leave since int
//cannot add double to int
            hash = hash * 31 + ((Double)gpa).hashCode();
            return hash;
    }
```

**OR**

```
public int hashCode()
    {
```

```
        return Objects.hash(studentLoans, gpa);
    }
```

## Upcasting and Downcasting:

The right side should be less than or equal left side.

We can not instantiate the interface.

**Will it compile:**

- **Check the static types,** do they all match:
  - Are you only calling the methods of the static type?
  - Are you only passing in parameters of(or lower than) the expected static type.( You can upcast here, but not implicity downcast)
  - Is the left side >= the right?
- Will it maybe crash:
  - Did you have to explicitly downcast to call a method.
  - Will it maybe work, but you don't know for sure because you didn't check?

## Super and Subclass:

```
public class Vehicle{

    private int maxSpeed=120;

    public Vehicle(int maxSpeed){
        this.maxSpeed=maxSpeed;
    }

    public void vroom(){
        Sytem.out.println("Vromm vrom")
    }
    // Override the equals method
    public boolean equals(Object o){
      if (o==null){return false;}
      if (o.getClass()!=this.getClass()){return false;}
      Vehicle t=(Vehicle)o;
      return t.maxSpeed==maxSpeed;
    }

    // Override toString method
    public String toString(){
        return "The Vehicle speed: "+ maxSpeed;
    }
}

public class Car extends Vehicle{
    private int doors;

    public Car(int doors,int maxSpeed){
        super(maxSpeed);
        this.doors=doors;
```

```
    }

    public void display(){
        System.out.println(super.maxSpeed)
    }

    public void vroom(){
        super.vrom();
    }
    // Override equals method
    public boolean equals(Object o){
        return super.equals(o) && ((Car)o).doors==doors;
    }

    // Override toString method
    public String toString(){
        return super.toString()+"The number of doors"+doors;
    }

}
```

## Comparable && Comparator:

This will compare the Objects and sort them. We need to make a separate class for Comparator which they call functional interface which can hold only on abstract method.

```
 // important note that Comparable is only input one Object
public class Student implements Comparable<Student>{

    private String lastName;
    private String firstName;
    private int age;
    private double gpa;

    public int compareTo(Student other){
        return lastName.compareTo(other.lastName);
    }
}

// Comparator implements two Objects
public class StudentAgeComparator implements Comparator<Student>{
   public int compare(Student s1, Student s2)
   {
      return s1.age() - s2.age(); //compare ascending order
   }
}

public class StudentGpaComparator implements Comparator<Student>
{
    //compare reverse order
   public int compare(Student s1, Student s2)
   {
      if (s1.gpa() >s2.gpa())
         return -1;
      else if (s1.gpa() < s2.gpa())
         return 1;
```

```
      else
         return 0;
   }
}
```

for sorting we have to methods:

```
Collections.sort.(studentList);

Arrays.sort(studentArray);

Collections.sort(studentList, new StudentGpaComparator()); // we can specify which Comparator we want to use
```

## Lambda:

Unnamed chunk of code I can pass around. It is a shortcut to implement a functional interface's method. We can make comparator in just one line.

```
Comparator<Student> comp2=(Student s1, Student s2)->{return s1.age()-s2.age();};
Collections.sort(studentList,comp2)

//second way
Comparator<Student> comp2=(s1,  s2)->s1.age()-s2.age();
Comparator<Student> comp3=Comparator.comparing(s->s.age());
Comparator<Student> comp4=Comparator.comparing(s::age());

// Third way
Collections.sort(studentList,(s1,  s2)->s1.age()-s2.age())

Funtion<Student,String>f=Student::getName; // This have a return types
Consumer<String>p=System.out::println; // Consumer don't have return types
Consumer<String>p=s ->System.out.println(s);
```

## Predicate:

```
public static void usePredicate(Predicate<Student> pred, Student s)
{
    if(pred.test(s))
System.out.println("yay");
else
    System.out.println("no!");
}
```
